

Pyranometers and pyrgeometers to measure all four components of the radiation balance (Photo: A. Christen)

## 08 Net all-wave radiation

## Learning objectives

---

- Be able to formulate the net-effect of all radiative exchange processes for surfaces.
- Describe which surface and geometric properties control radiative exchange.
- Be able to interpret graphs/figures of net-radiative exchange over diurnal and annual scales.

## Net short-wave and net long-wave

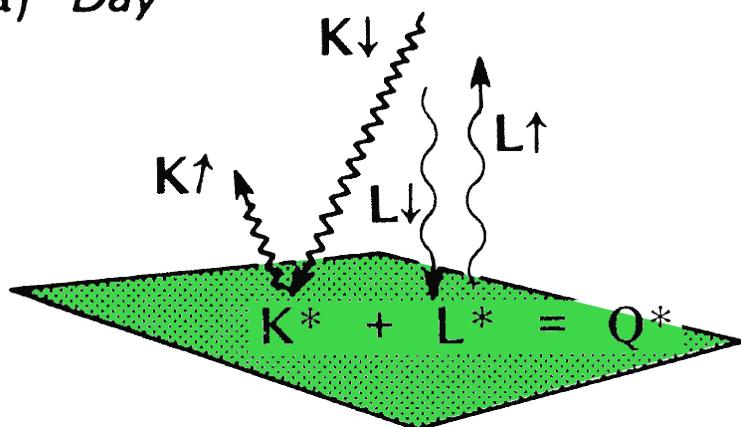

Net all-wave radiation ( $Q^*$ ) of a surface is the sum of the **net short-wave radiation ( $K^*$ )** and **net long-wave radiation ( $L^*$ )**:

Absorbed : available energy for other processes

# Net radiation for a flat surface

(a) Day

**Net all-wave radiation ( $Q^*$ )** is the sum of the **net short-wave radiation ( $K^*$ )** and **net long-wave radiation ( $L^*$ )**:

$$\begin{aligned} K^* &= K\downarrow - K\uparrow \\ &= K\downarrow(1 - \alpha) \end{aligned} \quad \star$$

$$\begin{aligned} L^* &= L\downarrow - L\uparrow \\ &= L\downarrow - [\varepsilon_o \sigma T_o^4 + L\downarrow(1 - \varepsilon_o)] \end{aligned}$$

$$\begin{aligned} Q^* &= K^* + L^* \\ &= K\downarrow(1 - \alpha) + \varepsilon_o L\downarrow - \varepsilon_o \sigma T_o^4 \end{aligned} \quad \star$$

$$K_{\downarrow}(1 - \alpha) + \varepsilon_o L_{\downarrow} - \varepsilon_o \sigma T_o^4$$

Which are the surface properties that impact  $Q^*$ ?

Which are the inputs of radiation?

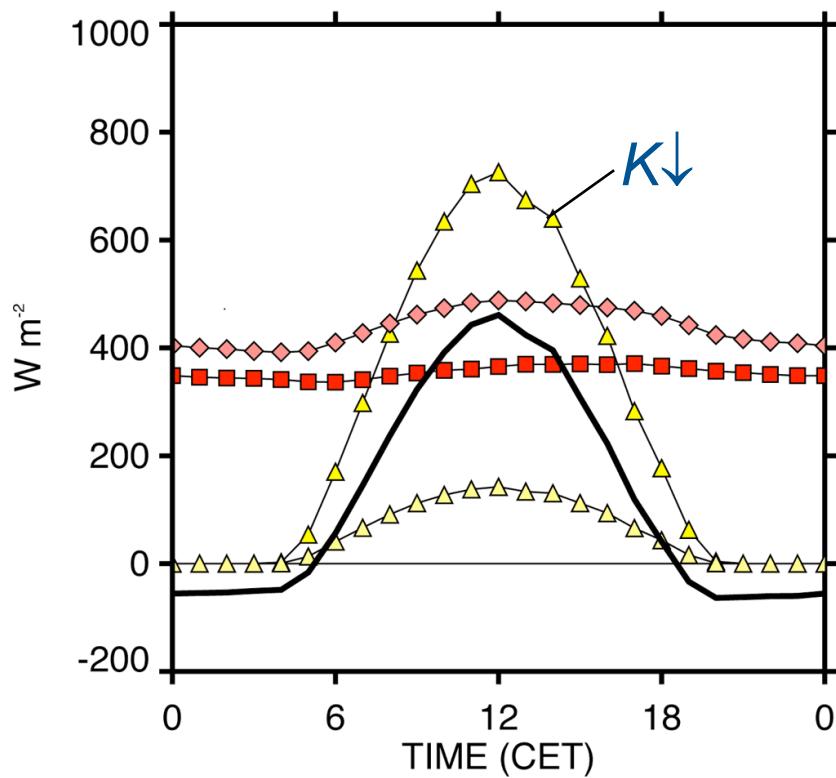

The range of values is lessened by the fact that the effects of  $\alpha$  and  $T_o$  tend to partially offset each other.

Clouds reduces extremes because they decreases  $K_{\downarrow}$  and increases  $L_{\downarrow}$ .

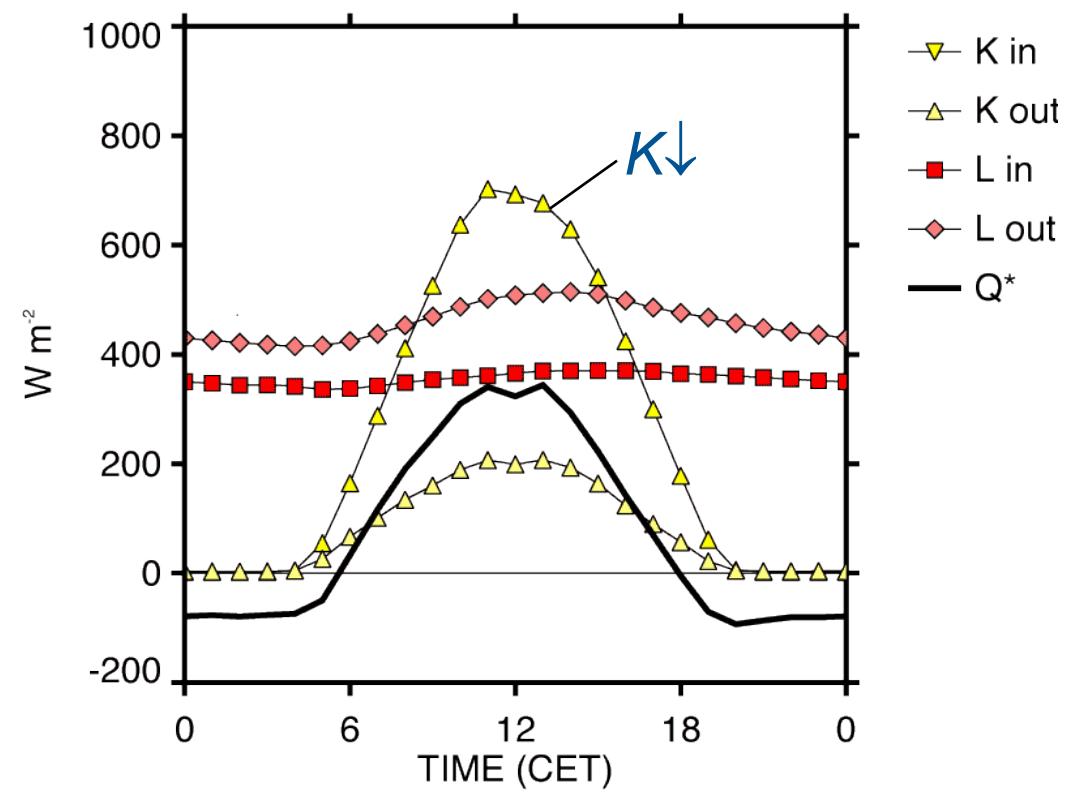

# Simultaneously measured $Q^*$ - different surface properties

Grass

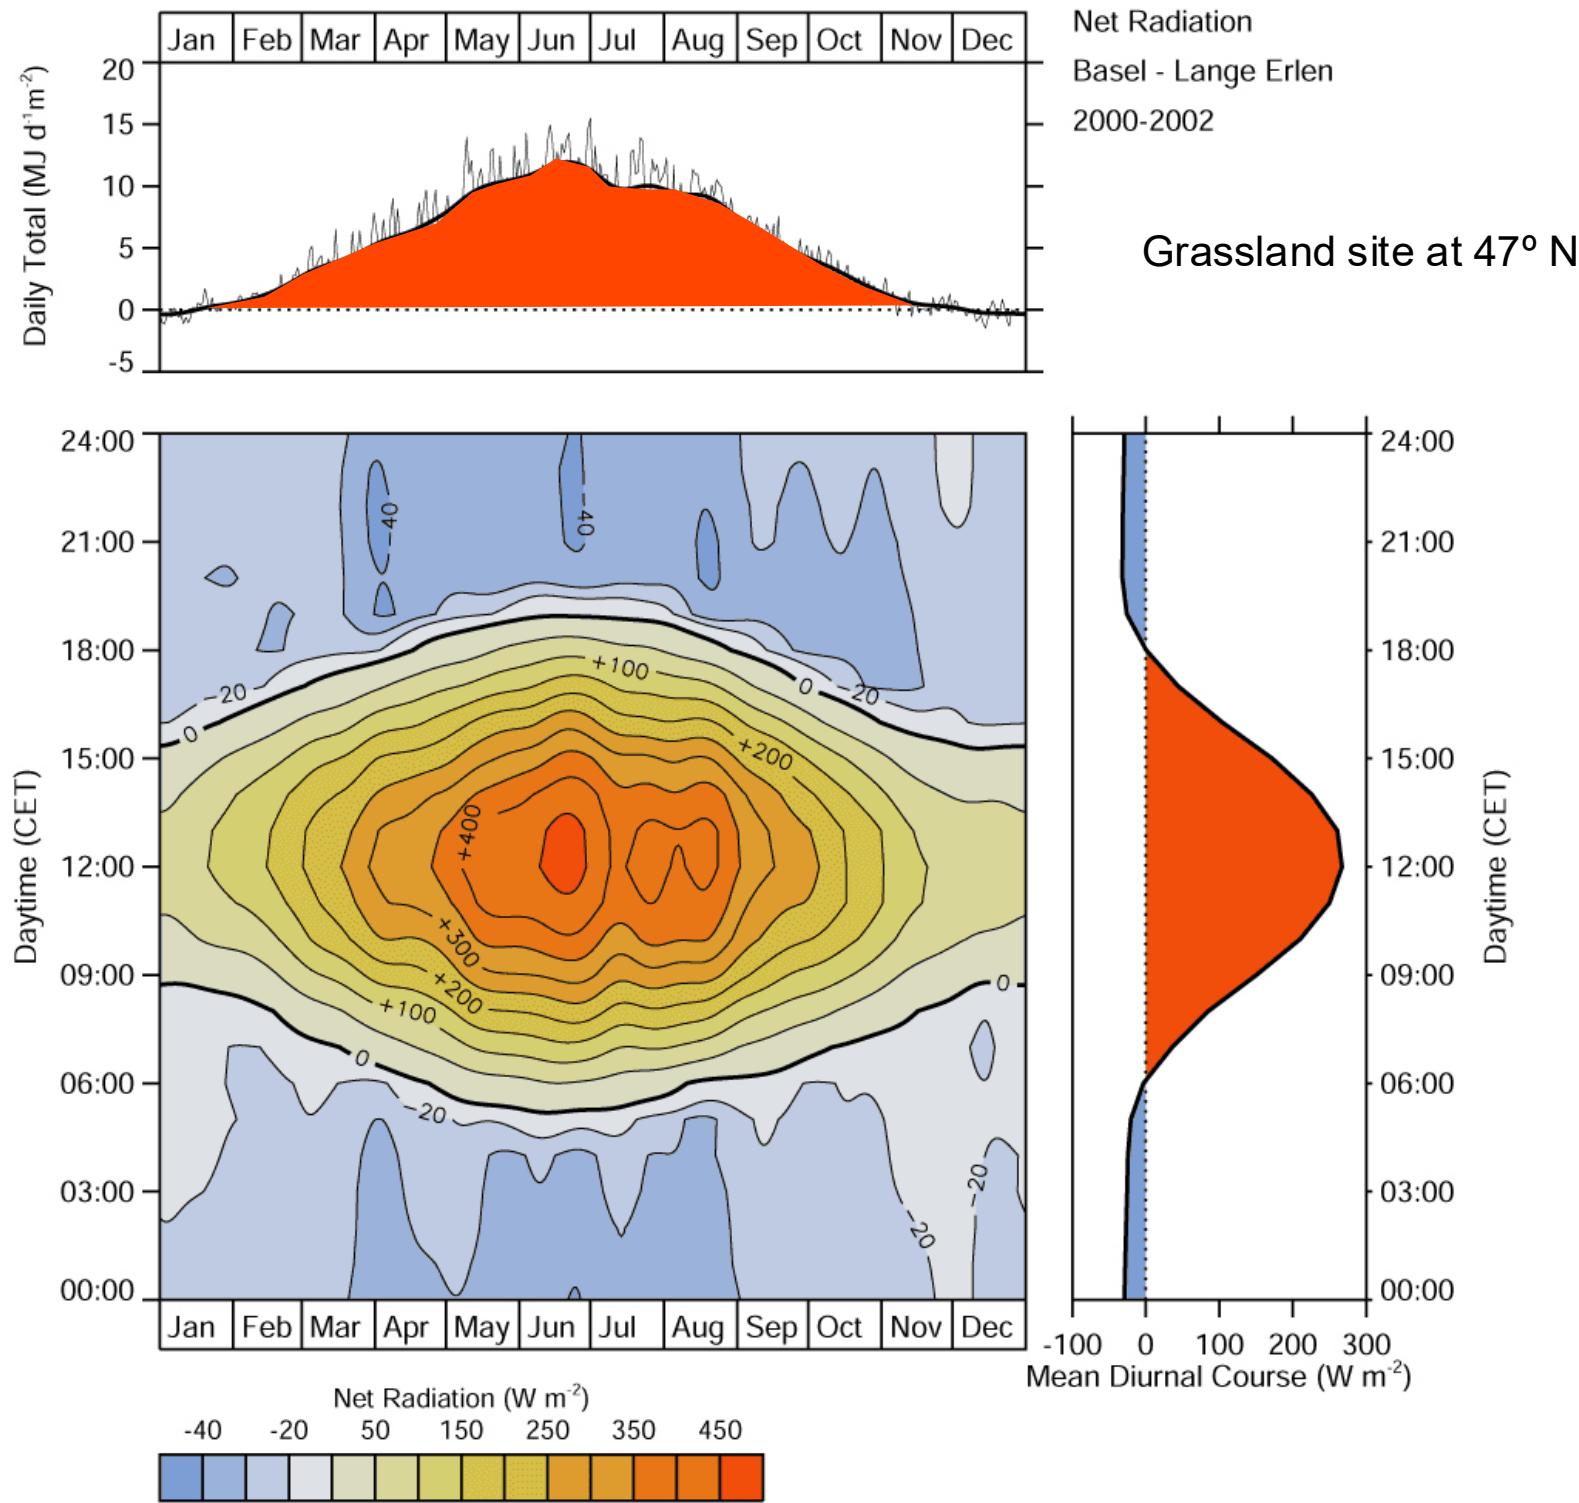

$$Q^* = 12.6 \text{ MJ m}^{-2} \text{ day}^{-1}$$

Parking lot

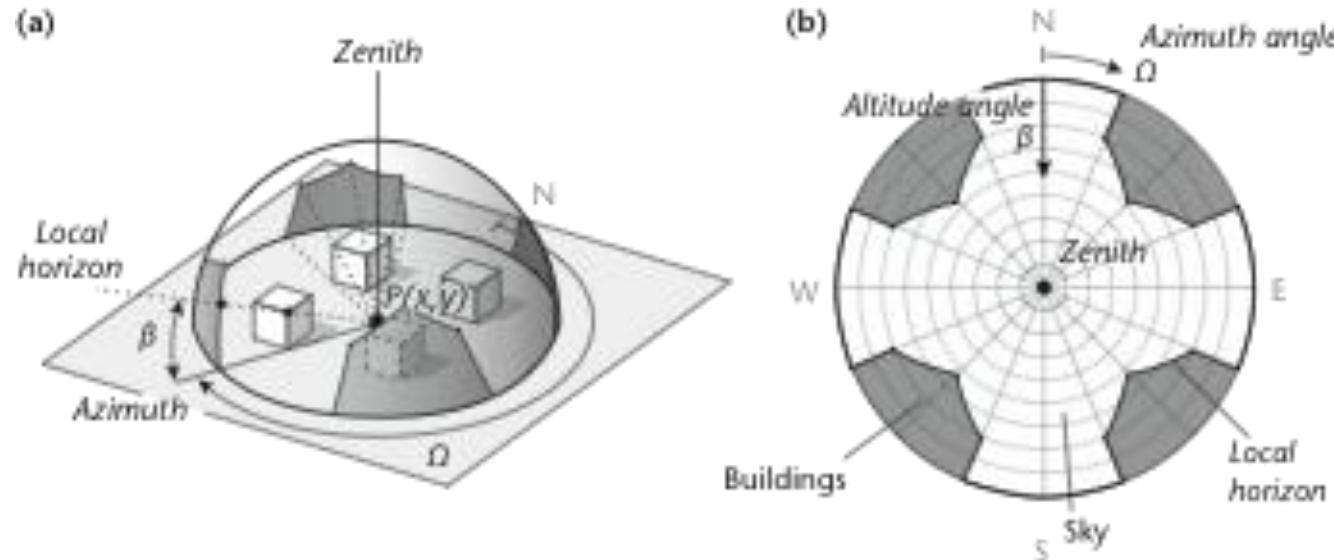

$$Q^* = 6.4 \text{ MJ m}^{-2} \text{ day}^{-1}$$

# View factors

A View factor refers to the fraction of radiation leaving one object that is intercepted by another object.

- Can be interpreted as fraction of one object's view (usually hemispherical) that is occupied by another object.
- The view of the sky from an object (**sky view factor**,  $\psi_{sky}$ ) is significant in quantifying long-wave exchange in complex configurations:

# Examples of sky view factors

Golden Gate Bridge  
San Francisco (US)  
(37,81008°, -122,47643°)  
**SVF = 0.87**

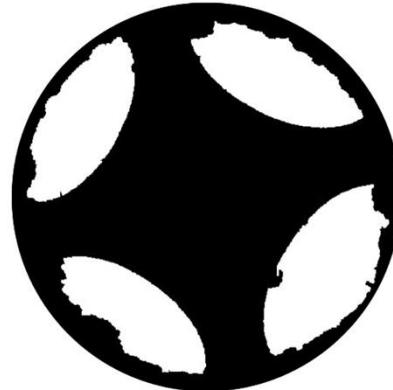

Eiffel Tower  
Paris (FR)  
(48,85283°, 2,34940°)  
**SVF = 0.42**

Time Square  
New York (US)  
(40,75734°, -73,98831°)  
**SVF = 0.37**

Singapore Zoo  
Singapore (Asia)  
(1,40290°, 103,79545°)  
**SVF = 0.19**

## Net radiation of two-sided object

A leaf is a 2-sided object so the simple incoming ( $\downarrow$ ) and outgoing ( $\uparrow$ ) consideration for the ground is insufficient - this has to be done on both sides, top (t) and bottom (b), and transmission is relevant:

(a)

T.R. Oke (1987): 'Boundary Layer Climates' 2<sup>nd</sup> Edition, with permission by author

$$Q^* = K^* + L^*$$

$$K^* = K_{in}(t) + K_{in}(b) - K_{out}(t) - K_{out}(b) - K_{trans}(t) - K_{trans}(b)$$

$$L^* = L_{in}(t) + L_{in}(b) - L_{out}(t) - L_{out}(b)$$

## Take home points

---

- Surface properties in the net all-wave budget tend to partially offset each other - in particular albedo and surface temperature.
- Temporal and spatial differences in net all-wave radiation are controlled by the distribution of **short-wave irradiance**, **atmospheric conditions** (clouds) and **surface properties**.
- Net all-wave radiative exchange of two-sided and 3D objects needs to consider distributions of radiative fluxes surrounding the object.
